

HOMEWORL03 – PYBANK & PYPOLL

PYBANK

OUTPUT FILE:

The output file will describe the overall Profit Analysis based on the CSV sent. Please find below a printout of the TXT file generated.

Financial Analysis

```
-----  
Total Months: 86  
Total: 38382578.0  
Average Change: 446309.05  
Greatest Increase in Profits: Feb-2012 ($1170593)  
Greatest Decrease in Profits: Sep-2013 ($-1196225)
```

CODE:

Although the code has comments, I have divided it into three main parts:

- Read the CSV File

```
1  import csv  
2  file_path = 'Resources/budget_data.csv'  
3  
4  greatestIncrease = [str(0),0.0]  
5  greatestDecrease = [str(0),0.0]  
6  totalAmount = 0.0  
7  numberMonths = 0  
8  print(type(totalAmount))  
9  
10 with open(file_path) as csvfile:  
11     csvreader = csv.reader(csvfile,delimiter=',')  
12
```

- Calculate and iterate across the CSV File

```
15  
16     #Iterate over the file  
17     for row in csvreader:  
18         numberMonths += 1  
19         totalAmount += float(row[1])  
20         #Calculate Greatest Increase and Decrease  
21         if float(greatestIncrease[1]) < float(row[1]):  
22             greatestIncrease = row  
23         if float(greatestDecrease[1]) > float(row[1]):  
24             greatestDecrease = row  
25  
26 averageChange = totalAmount/numberMonths  
27
```

- Print and Create output file

```

27
28 #Writing TXT File
29 output_file = "Analysis/output.txt"
30
31 with open (output_file,'w') as output:
32
33     output.write("Financial Analysis\n")
34     output.write("-----\n")
35     output.write(f'Total Months: {numberMonths}\n')
36     output.write(f'Total: {totalAmount}\n')
37     output.write(f'Average Change: {round(averageChange,2)}\n')
38     output.write(f'Greatest Increase in Profits: {str(greatestIncrease[0])} ({str(greatestIncrease[1])})\n')
39     output.write(f'Greatest Decrease in Profits: {str(greatestDecrease[0])} ({str(greatestDecrease[1])})')
40
41 #Print at the terminal
42 print(f'Financial Analysis\n-----\nTotal Months: {numberMonths}\nTotal: {totalAmount}\nAverage Change: {round(averageChange,2)}\nGreatest Increase in Profits: {str(greatestIncrease[0])} ({str(greatestIncrease[1])})\nGreatest Decrease in Profits: {str(greatestDecrease[0])} ({str(greatestDecrease[1])})')
43
44

```

PYPOLL

OUTPUT FILE:

The output file describes the overall results of a Political campaign, highlighting the total number of votes, the % of each candidate, and the Winner of the election.

Elections Results

```
-----
Total Votes: 3521001
-----
```

```
Khan: 63.0% (2218231)
Correy: 20.0% (704200)
Li: 14.0% (492940)
O'Tooley: 3.0% (105630)
-----
```

```
Winner: Khan
-----
```

CODE:

The strategy behind this code is different from the one used in the example above. Since the goal of this essay was not to use Pandas to summarize the data somehow and get the results, I have coded a function that runs all the main calculations we will need based on the "Candidate Name Field."

- Calculation & Output Function:
 - Iterate Part

```

3  def elections(data, output_file):
4      #initiate variables
5      candidate_list = []
6      candidate_count= []
7      totalvotes = 0
8      #iterate over the list
9      for x in data:
10         totalvotes+=1
11         #verify if it exist in the list
12         if x not in candidate_list:
13             #append new candidate
14             candidate_list.append(x)
15             candidate_count.append(int(0))
16         #count based on candidate list
17         for i in range(len(candidate_list)):
18             if x == candidate_list[i]:
19                 candidate_count[i] = candidate_count[i]+1
20     #defining %
21     percentages = [round((number/totalvotes)*100,3) for number in candidate_count]
22
23     #Defining Winner
24     winner_percentage = 0.0
25
26     for i in range(len(percentages)):
27         if percentages[i] > winner_percentage:
28             winner_percentage= percentages[i]
29             winner = candidate_list[i]
30

```

○ Output Part:

```

31
32     #Print Results
33     print("Elections Results")
34     print("-----")
35     print(f'Total Votes: {totalvotes}')
36     print("-----")
37     for i in range(len(candidate_list)):
38         print(f'{candidate_list[i]}: {percentages[i]}% ({candidate_count[i]})')
39     print("-----")
40     print(f'Winner: {winner}')
41     print("-----")
42
43     #Create output file
44     with open(output_file,'w') as output:
45         output.write("Elections Results\n")
46         output.write("-----\n")
47         output.write(f'Total Votes: {totalvotes}\n')
48         output.write("-----\n")
49         for i in range(len(candidate_list)):
50             output.write(f'{candidate_list[i]}: {percentages[i]}% ({candidate_count[i]})\n')
51         output.write("-----\n")
52         output.write(f'Winner: {winner}\n')
53         output.write("-----")
54

```

- Read the file and Function application:

```

55
56     file_path = "Resources/election_data.csv"
57
58     output_path = "Analysis/election_results.txt"
59
60     candidate = []
61
62     with open(file_path) as csvfile:
63         csvreader = csv.reader(csvfile, delimiter = ',')
64
65         csv_header = next(csvreader)
66
67         #iterate over the file
68         for row in csvreader:
69             candidate.append(row[2])
70
71     elections(candidate,output_path)
72
73
74
75

```
